## The essential Set of Variables to be monitored

For the design of an efficient observation system for Africa the interoperability with other networks, but also the specific continental context need to be considered. As one of the first steps we identified the essential set of variables which need to be monitored in Africa. We defined the 'ideal' set of variables, including all climatic, oceanic and biodiversity

variables listed by WMO, GOOS and GEOBON. Those were listed in an online tool. 210 experts were consulted to rate the variables on their 'relevance', 'feasibility' and 'costs', in the African context. We received 40 answers, which were used to compute a score for each variable. 42 variables were identified as 'essential'. Figure 1-4 taken from López-Ballesteros et al (2018)

## Background

Climate change is threatening ecosystems and societies in Africa. At the same time, population growth causing land-use change, increased energy demand and the development of industry and transport infrastructure contributes to increasing greenhouse gas (GHG) emissions.

In global comparison carbon (C) emissions of Africa from fossil fuel and cement production are still very low (3.6% in 2014; Boden et al 2017). Regarding the African continent emissions from land use change and forestry account for more than one third of the total emissions (Valentini et al 2014).

Scientific advice on GHG emissions with regard to agricultural production is important for Africa to improve the environmental reporting and policies, by also considering food security demands. For scientific analysis and advice, sufficient qualitative and quantitative data about GHG sources and sinks are essential.

## Inventory of RIs across Africa

We compiled an inventory of the environmental observation stations, measuring any of the identified variables, through literature search and consulting relevant projects and experts. 47 observation infrastructures were identified. For the ground- based and sea-born observation sites, we captured the location and operation status (as far as available). Observation stations are heterogeneously distributed, especially those for atmospheric and GHG observations. The density of stations is relatively high in parts of Northern, Western and Southern Africa, but still does not reach the level of other continents. For the sea-born station, the pattern is similar. We further plotted the stations to biomes and the main

anthromes. We show that smaller biomes, such as mangroves are underrepresented. Moreover a significant correlation of population and station density was found.

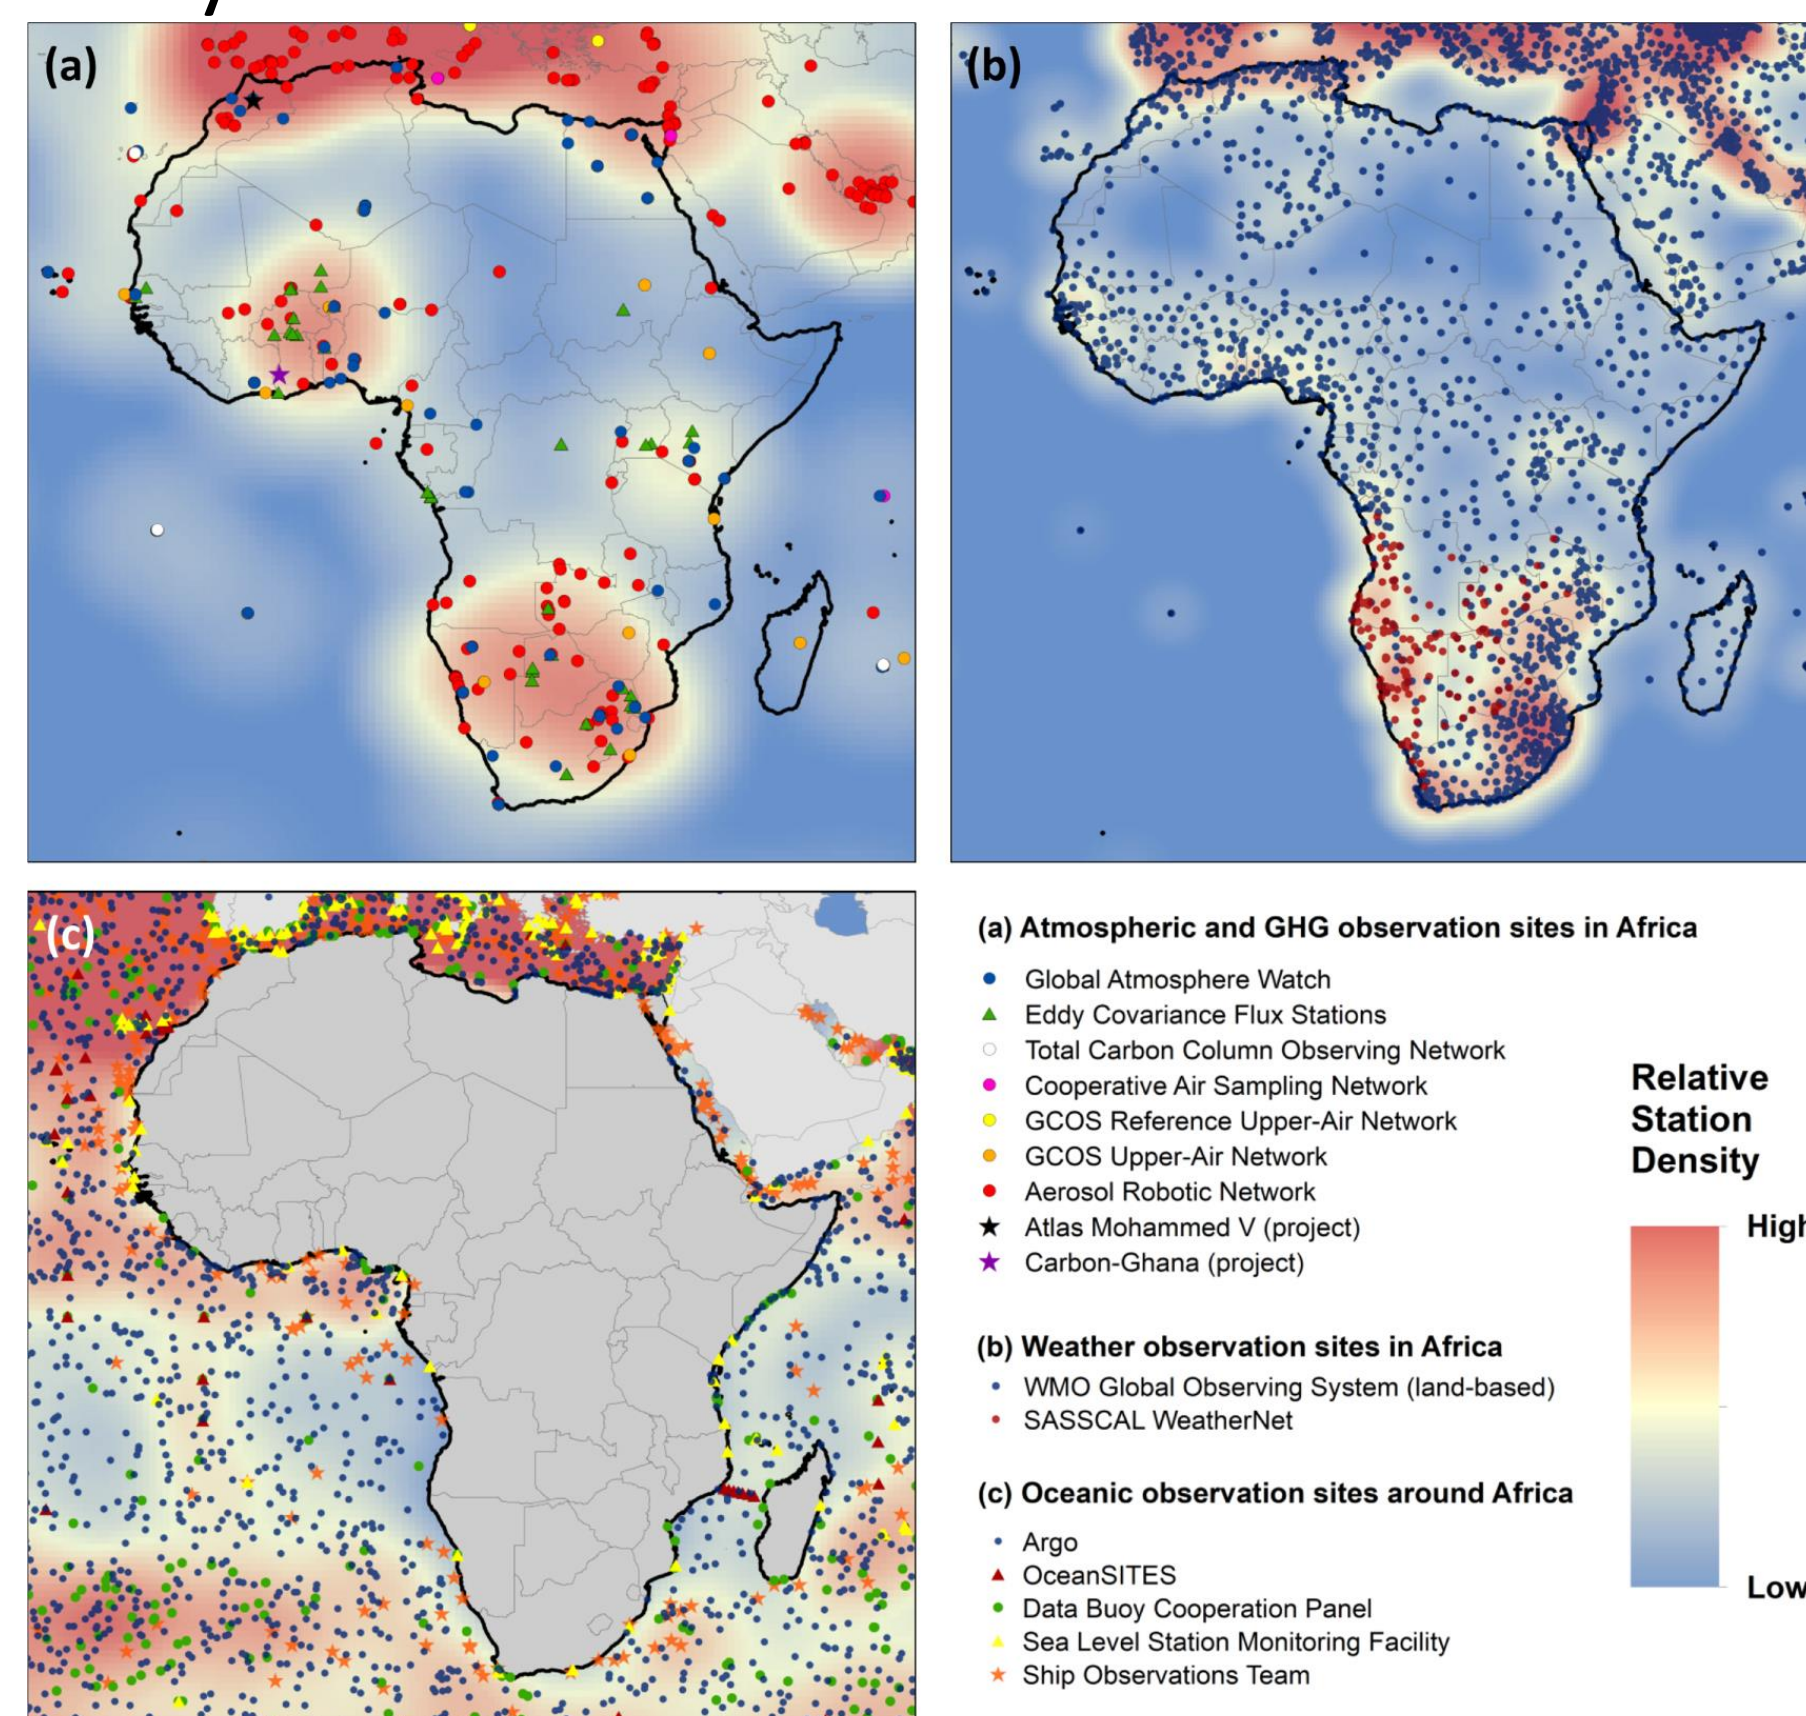

Figure 3: Observation stations and density of selected networks.

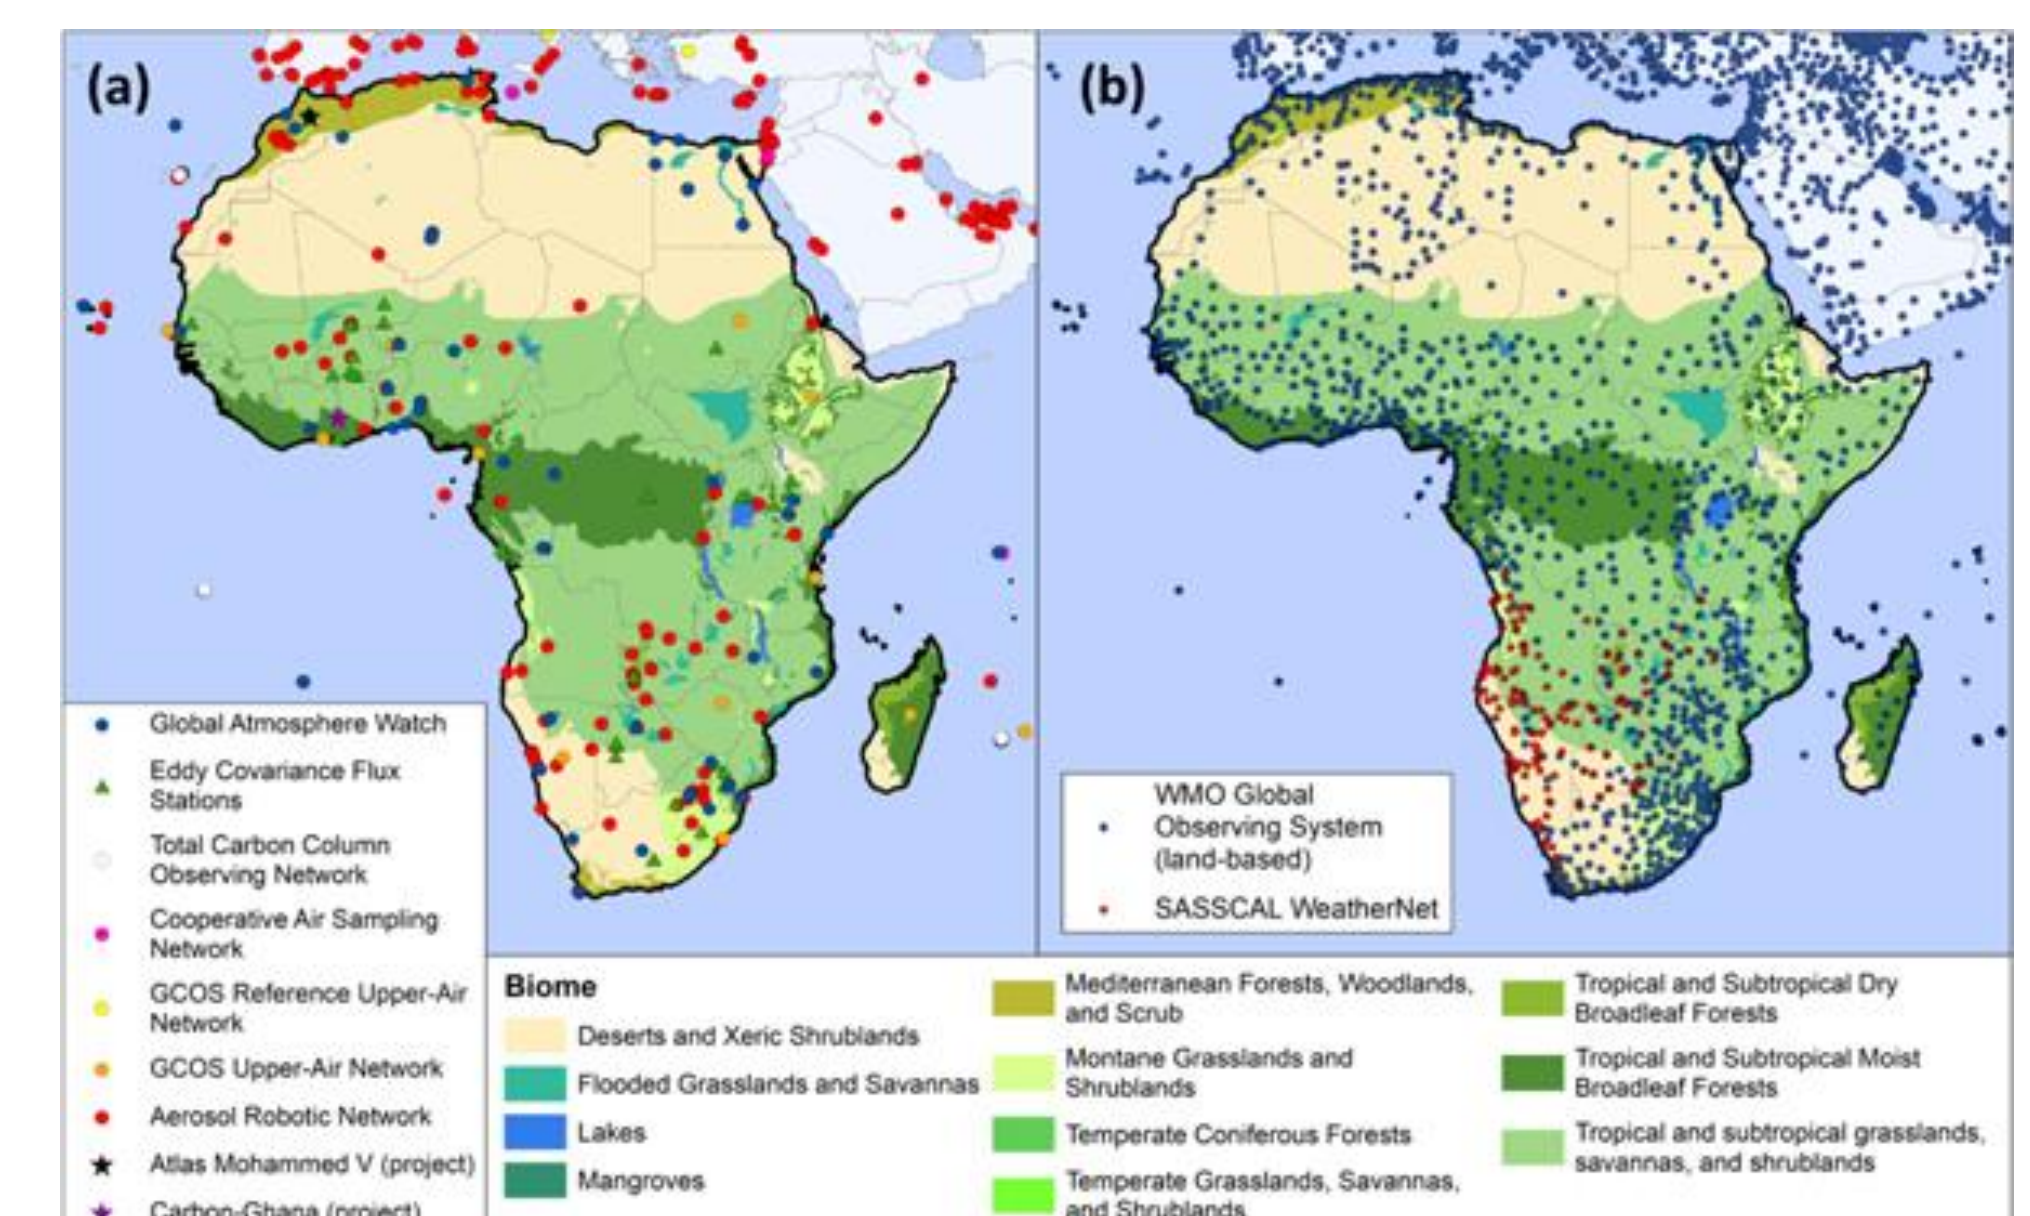

Figure 4: Observing stations of selected networks for (a) GHG and aerosols and (b) weather observation against the major biomes (Olson et al 2001) of the African continent.
